- 5 Hash-based MAC
- 6 Information-Theoretic MACs

# **Integrity and Authentication**

### The Syntax of MAC

- key k, tag t, a bit b means valid if b = 1; invalid if b = 0.
- **Key-generation** algorithm  $k \leftarrow \text{Gen}(1^n), |k| \ge n$ .
- Tag-generation algorithm  $t \leftarrow \mathsf{Mac}_k(m)$ .
- **Verification** algorithm  $b := Vrfy_k(m, t)$ .
- Message authentication code:  $\Pi = (Gen, Mac, Vrfy)$ .
- Basic correctness requirement:  $Vrfy_k(m, Mac_k(m)) = 1$ .

# **Security of MAC**

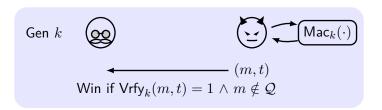

- Intuition: No adversary should be able to generate a valid tag on any "new" message¹ that was not previously sent.
- Replay attack: Copy a message and tag previously sent. (excluded by only considering "new" message)
  - Sequence numbers: receiver must store the previous ones.
  - Time-Stamps: sender/receiver maintain synchronized clocks.
- Existential unforgeability: Not be able to forge a valid tag on any message.
  - **Existential forgery**: at least one message.
  - **Selective forgery**: message chosen *prior* to the attack.
  - Universal forgery: any given message.
- Adaptive chosen-message attack (CMA): be able to obtain tags on *any* message chosen adaptively *during* its attack.

<sup>&</sup>lt;sup>1</sup>A stronger requirement is concerning new message/tag pair.

# **Definition of MAC Security**

The message authentication experiment  $\mathsf{Macforge}_{\mathcal{A},\Pi}(n)$ :

- **2**  $\mathcal{A}$  is given input  $1^n$  and oracle access to  $\mathrm{Mac}_k(\cdot)$ , and outputs (m,t).  $\mathcal Q$  is the set of queries to its oracle.
- $\mbox{3} \mbox{ Macforge}_{\mathcal{A},\Pi}(n) = 1 \iff \mbox{Vrfy}_k(m,t) = 1 \, \wedge \, m \notin \mathcal{Q}.$

#### **Definition 1**

A MAC  $\Pi$  is existentially unforgeable under an adaptive CMA if  $\forall \ \mathrm{PPT} \ \mathcal{A}$ ,  $\exists \ \mathrm{negl} \ \mathrm{such \ that}$ :  $\Pr[\mathsf{Macforge}_{\mathcal{A},\Pi}(n)=1] \leq \mathsf{negl}(n)$ .

### Real World Case

### The 802.11b Insecure MAC<sup>2</sup>

Consider a variant of WiFi encryption in 802.11b WEP (Wired Equivalent Privacy). Let F be a PRF with a 32-bit length output. Let CRC32 be an error-detecting code outputting a 32-bit string. Define the following MAC scheme:

$$S(k,m) := (r \leftarrow \{0,1\}^n, t \leftarrow F(k,r) \oplus \mathsf{CRC32}(m))$$
 
$$V(k,m,(r,t)) := 1 \quad \text{if} \quad t = F(k,r) \oplus \mathsf{CRC32}(m)$$

- Different messages may have the same CRC32 output.
- Attacker can learn F(k,r) from a valid tag, and then output  $(m',(r,F(k,r)\oplus \mathsf{CRC32}(m'))).$

<sup>&</sup>lt;sup>2</sup>from BonehShoup v0.5 p.234

### Questions

### Suppose $\langle S, V \rangle$ are CMA-secure, are $\langle S', V' \rangle$ secure?

$$S'_k(m) = (S_k(m), m), \ V'_k(m, (t_1, t_2)) = V_k(m, t_1) \wedge t_2 = m$$

$$S'_{k_1,k_2}(m) = (S_{k1}(m), S_{k_2}(m)) V'_{k_1,k_2}(m, (t_1, t_2)) = V_{k1}(m, t_1) \wedge V_{k_2}(m, t_2)$$

$$S_k'(m) = (S_k(m), S_k(m))$$
 
$$V_k'(m, (t_1, t_2)) = \left\{ \begin{array}{l} V_k(m, t_1) & \text{if } t_1 = t_2 \\ 0 & \text{otherwise} \end{array} \right.$$

$$S'_k(m) = (S_k(m), S_k(0^n))$$

$$V'_k(m, (t_1, t_2)) = V_k(m, t_1) \wedge V_k(0^n, t_2)$$

$$S_k'(m) = S_k(m), \ V_k'(m,t) = \left\{ \begin{array}{ll} V_k(m,t) & \text{if } m \neq 0^n \\ 1 & \text{otherwise} \end{array} \right.$$

■ 
$$S_k'(m) = S_k(m)$$
 without the LSB  $V_k'(m,t) = V_k(m,t\|0) \ \lor \ V_k(m,t\|1)$ 

# **MAC Applications** <sup>3</sup>

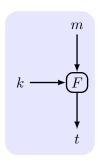

- Browser cookie: includes a MAC tag of the user's account generated by the web server, against the attacker forging others' cookies.
- TCP SYN cookie: The server's initial sequence number includes a MAC tag of the client's IP address, port number and some other values generated by the server, against "half-open" DDoS attack in TCP handshake.
- Timed one-time passwords:  $p = \text{Mac}_k(T)$ , where k is the key shared between the user and the service provider, T is the current date + time (usually rounded to the nearest 30 seconds.) The attacker who learns the current p can not gain access to your account in the future.

- 3 CBC-MAC
- **4** Collision-Resistant Hash Functions
- 5 Hash-based MAC
- 6 Information-Theoretic MACs

### **Constructing Secure MAC**

#### **Construction 2**

- $\blacksquare$  F is PRF. |m|=n.
- $Gen(1^n)$ :  $k \leftarrow \{0,1\}^n$  u.a.r.
- $\blacksquare \operatorname{\mathsf{Mac}}_k(m) \colon t := F_k(m).$
- $\qquad \text{Vrfy}_k(m,t) \colon 1 \iff t \stackrel{?}{=} F_k(m).$

#### Theorem 3

If F is a PRF, Construction is a secure fixed-length MAC.

#### Lemma 4

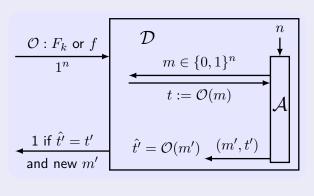

**Truncating MACs based on PRFs**: If F is a PRF, so is  $F_k^t(m) = F_k(m)[1, \ldots, t]$ .

### **Proof of Secure MAC from PRF**

**Idea**: Show  $\Pi$  is secure unless  $F_k$  is not PRF by reduction.

#### Proof.

D distinguishes  $F_k$ ;  $\mathcal{A}$  attacks  $\Pi$ .

# Proof of Secure MAC from PRF (Cont.)

#### Proof.

(1) If true random f is used, t=f(m) is uniformly distributed.

$$\Pr[D^{f(\cdot)}(1^n) = 1] = \Pr[\mathsf{Macforge}_{A\ \tilde{\Pi}}(n) = 1] \leq 2^{-n}.$$

(2) If  $F_k$  is used, conduct the experiment  $\mathsf{Macforge}_{\mathcal{A},\Pi}(n)$ .

$$\Pr[D^{F_k(\cdot)}(1^n) = 1] = \Pr[\mathsf{Macforge}_{\mathcal{A},\Pi}(n) = 1] = \varepsilon(n).$$

According to the definition of PRF,

$$\left| \Pr[D^{F_k(\cdot)}(1^n) = 1] - \Pr[D^{f(\cdot)}(1^n) = 1] \right| \ge \varepsilon(n) - 2^{-n}.$$

### **Extension to Variable-Length Messages**

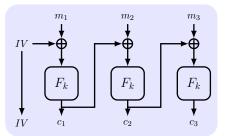

# For variable-length messages, would the following suggestions be secure?

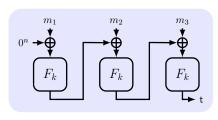

- Suggestion 1: XOR all the blocks together and authenticate the result.  $t := \mathsf{Mac}_k'(\oplus_i m_i)$ .
- Suggestion 2: Authenticate each block separately.  $t_i := \text{Mac}'_k(m_i)$ .
- Suggestion 3: Authenticate each block along with a sequence number.  $t_i := \mathsf{Mac}_k'(i||m_i)$ .

### **Content**

- 1 Message Authentication Codes (MAC) Definitions
- **2** Constructing Secure MAC
- 3 CBC-MAC
- **4** Collision-Resistant Hash Functions
- 5 Hash-based MAC
- 6 Information-Theoretic MACs

### Constructing Fixed-Length CBC-MAC

Modify CBC encryption into CBC-MAC:

- Change random IV to encrypted fixed  $0^n$ , otherwise: Q: query  $m_1$  and get  $(IV, t_1)$ ; output  $m_1' = IV' \oplus IV \oplus m_1$  and  $t' = \underline{\hspace{1cm}}$ .
- Tag only includes the output of the final block, otherwise: Q: query  $m_i$  and get  $t_i$ ; output  $m_i' = t_{i-1}' \oplus t_{i-1} \oplus m_i$  and  $t_i' = \underline{\hspace{1cm}}$ .

# Constructing Fixed-Length CBC-MAC (Cont.)

#### **Construction 5**

- a PRF F and a length function  $\ell$ .  $|m| = \ell(n) \cdot n$ .  $\ell = \ell(n)$ .  $m = m_1, \ldots, m_\ell$ .
- $Gen(1^n)$ :  $k \leftarrow \{0,1\}^n$  u.a.r.
- lacksquare Mac $_k(m)$ :  $t_i:=F_k(t_{i-1}\oplus m_i), t_0=0^n$ . Output  $t=t_\ell$ .
- $Vrfy_k(m,t)$ :  $1 \iff t \stackrel{?}{=} Mac_k(m)$ .

#### Theorem 6

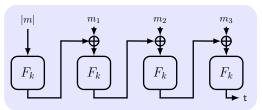

If F is a PRF, Construction is a secure **fixed-length** MAC.

### Not for variable-length message:

Q: For one-block message m with tag t, adversary can append a block \_\_\_\_ and output tag t.

# Secure Variable-Length MAC

- Input-length key separation:  $k_{\ell} := F_k(\ell)$ , use  $k_{\ell}$  for CBC-MAC.
- **Length-prepending**: Prepend m with |m|, then use CBC-MAC.

■ Encrypt last block (ECBC-MAC): Use two keys  $k_1, k_2$ . Get t with  $k_1$  by CBC-MAC, then output  $\hat{t} := F_{k_2}(t)$ .

Q: To authenticate a voice stream, which approach do you prefer?

### **MAC Padding**

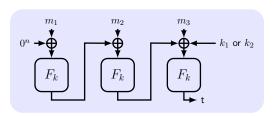

Padding must be invertible!

$$m_0 \neq m_1 \Rightarrow \mathsf{pad}(m_0) \neq \mathsf{pad}(m_1).$$

**ISO**: pad with "100...00". Add dummy block if needed.

Q: What if no dummy block?

CMAC (Cipher-based MAC from NIST): key=  $(k, k_1, k_2)$ .

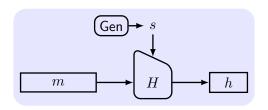

- No final encryption: extension attack thwarted by keyed XOR.
- No dummy block: ambiguity resolved by use of  $k_1$  or  $k_2$ .

### **Content**

- 1 Message Authentication Codes (MAC) Definitions
- **2** Constructing Secure MAC
- 3 CBC-MAC
- **4** Collision-Resistant Hash Functions
- 5 Hash-based MAC
- 6 Information-Theoretic MACs

# **Defining Hash Function**

#### **Definition 7**

A hash function (compression function) is a pair of PPT algorithms (Gen, H) satisfying:

- a key  $s \leftarrow \mathsf{Gen}(1^n)$ , s is **not kept secret**.
- $\blacksquare$   $H^s(x) \in \{0,1\}^{\ell(n)}$ , where  $x \in \{0,1\}^*$  and  $\ell$  is polynomial.

If  $H^s$  is defined only for  $x\in\{0,1\}^{\ell'(n)}$  and  $\ell'(n)>\ell(n)$ , then (Gen, H) is a **fixed-length** hash function.

# **Defining Collision Resistance**

- **Collision** in H:  $x \neq x'$  and H(x) = H(x').
- Collision Resistance: infeasible for any PPT alg. to find.

The collision-finding experiment  $\mathsf{Hashcoll}_{\mathcal{A},\Pi}(n)$ :

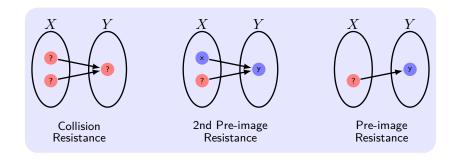

- $s \leftarrow \mathsf{Gen}(1^n).$
- $\mathbf{2}$   $\mathcal{A}$  is given s and outputs x, x'.

#### **Definition 8**

 $\Pi$  (Gen,  $H^s$ ) is **collision resistant** if  $\forall$  PPT  $\mathcal{A}$ ,  $\exists$  negl such that

$$\Pr[\mathsf{Hashcoll}_{\mathcal{A},\Pi}(n) = 1] \le \mathsf{negl}(n).$$

# Weaker Notions of Security for Hash Functions

- **Collision resistance**: It is hard to find  $(x, x'), x' \neq x$  such that H(x) = H(x').
- Second pre-image resistance: Given s and x, it is hard to find  $x' \neq x$  such that  $H^s(x') = H^s(x)$ .
- Pre-image resistance: Given s and  $y = H^s(x)$ , it is hard to find x' such that  $H^s(x') = y$ .

### Questions

#### H is CRHF. Is H' CRHF?

$$\blacksquare H'(m) = H(m) \oplus H(m \oplus 1^{|m|})$$

$$H'(m) = H(m) || H(0)$$

$$\blacksquare \ H'(m) = H(m) \| H(m)$$

$$\blacksquare H'(m) = H(m) \oplus H(m)$$

$$H'(m) = H(m[0, ..., |m| - 2])$$

$$H'(m) = H(m||0)$$

$$H'(m) = H(m)[0, ..., |m| - 1]$$

# **Applications of Hash Functions**

- Fingerprinting and Deduplication: H(alargefile) for virus fingerprinting, deduplication, P2P file sharing
- Merkle Trees:

```
H(H(H(file1), H(file2)), H(H(file3), H(file4))) fingerprinting multiple files / parts of a file
```

- **Password Hashing**: (salt, H(salt, pw)) mitigating the risk of leaking password stored in the clear
- **Key Derivation**: H(secret) deriving a key from a high-entropy (but not necessarily uniform) shared secret
- **Commitment Schemes**: H(info) hiding the committed info; binding the commitment to a info

# The "Birthday" Problem

#### The "Birthday" Problem

**Q**: "What size group of people do we need to take such that with probability 1/2 some pair of people share a birthday?" **A**: 23.

#### Lemma 9

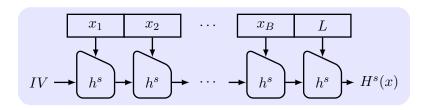

Choose q elements u.a.r from a set of size N, the probability that  $\exists \ i \neq j \ \text{with} \ y_i = y_j \ \text{is} \ \text{coll}(q,N)$ , then  $\text{coll}(q,N) \leq \frac{q^2}{2N}$ .

### How many different meaningful sentences are below?

It is hard/difficult/challenging/impossible to imagine/believe that we will find/locate/hire another employee/person having similar abilities/skills/character as Alice. She has done a great/super job.

A principle: The length of hash value should be long enough.

# The Merkle-Damgård Transform

#### **Construction 10**

Construct **variable-length** CRHF (Gen, H) from fixed-length (Gen, h) ( $2\ell$  bits  $\rightarrow \ell$  bits,  $\ell = \ell(n)$ ):

- Gen: remains unchanged
- $\blacksquare$  H: key s and string  $x \in \{0,1\}^*$ ,  $L = |x| < 2^{\ell}$ :
  - $B := \lceil \frac{L}{\ell} \rceil$  (# blocks). **Pad** x with 0s.  $\ell$ -bit blocks  $x_1, \ldots, x_B$ .  $x_{B+1} := L$ , L is encoded using  $\ell$  bits
  - $lacksymbol{z}_0 := IV = 0^\ell$ . For  $i=1,\ldots,B+1$ , compute  $z_i := h^s(z_{i-1} \| x_i)$

# Security of the Merkle-Damgård Transform

#### Theorem 11

If (Gen, h) is a fixed-length CRHF, then (Gen, H) is a CRHF.

#### Proof.

**Idea**: a collision in  $H^s$  yields a collision in  $h^s$ .

Two messages  $x \neq x'$  of respective lengths L and L' such that  $H^s(x) = H^s(x')$ . # blocks are B and B'.

 $x_{B+1} := L$  is necessary since **Padding with 0s** will lead to the same input with different messages.

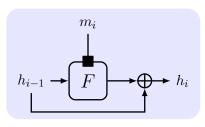

- 1  $L \neq L'$ :  $z_B || L \neq z_{B'} || L'$

So there must be  $x \neq x'$  such that  $h^s(x) = h^s(x')$ .

Security on MD transform variations in Homework.

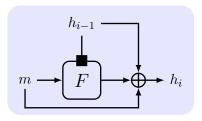

# **CRHF** from Block Cipher

Davies-Meyer (SHA-1/2, MD5)

$$h_i = F_{m_i}(h_{i-1}) \oplus h_{i-1}$$

Miyaguchi-Preneel (Whirlpool)

$$h_i = F_{h_{i-1}}(m_i) \oplus h_{i-1} \oplus m$$

#### Theorem 12

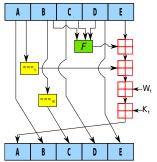

If F is modeled as an ideal cipher, then Davies-Meyer construction yields a CRHF.

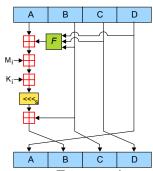

Q: what if  $h_i = F_{m_i}(h_{i-1})$  without XOR with  $h_{i-1}$ ?

Q: what if F is not ideal such that  $\exists x, F_k(x) = x$ ?

### Cryptographic Hash Functions: SHA-1 and MD5

SHA-1: MD5:

A,B,C,D and E are 32-bit words of the state; F is a nonlinear function that varies;  $\ll n$  denotes a left bit rotation by n places;  $W_t/M_t$  is the expanded message word of round t;  $K_t$  is the round constant of round t;  $\boxplus$  denotes addition modulo  $2^{32}$ .

- Finding a collision in 128-bit MD5 requires time  $2^{20.96}$
- lacksquare Finding a collision in 160-bit SHA-1 requires time  $2^{51}$

### **Content**

- 1 Message Authentication Codes (MAC) Definitions
- **2** Constructing Secure MAC
- 3 CBC-MAC
- **4** Collision-Resistant Hash Functions
- 5 Hash-based MAC
- 6 Information-Theoretic MACs

### Hash-and-MAC

#### **Construction 13**

 $(\widetilde{\mathsf{Gen}}, H)$  is a CRHF.  $(\mathsf{Gen}, \mathsf{Mac}, \mathsf{Vrfy})$  is a fixed-length MAC.

- $\operatorname{Gen}'(1^n)$ : (k,s).  $s \leftarrow \widetilde{\operatorname{Gen}}, k \leftarrow \operatorname{Gen}$ .
- $\blacksquare \operatorname{\mathsf{Mac}}'_{s,k}(m) \colon t := \operatorname{\mathsf{Mac}}_k(H^s(m)).$
- $\qquad \mathsf{Vrfy'}_{s,k}(m,t) \colon 1 \iff \mathsf{Vrfy}_k(H^s(m),t) = 1.$

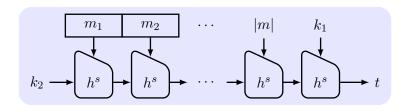

#### Theorem 14

The construction is a secure MAC for arbitrary-length messages.

Idea of proof: if the adversary has forged a tag on the "new message"  $m^{\ast}$ , then

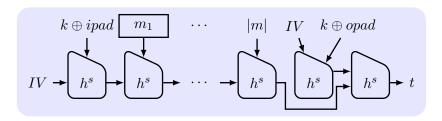

- Case 1: If there is a queried messages m such that  $H^s(m) = H^s(m^*)$ , then there is a collision in  $H^s$ .
- Case 2: If there is no queried messages m such that  $H^s(m) = H^s(m^*)$ , then the adversary has forged a valid tag on the "new message"  $H^s(m^*)$  for MAC.

# Nested MAC (NMAC)

- NMAC is a MAC using CRHF (MD transform) without using PRF.
- $k_2$  is not needed once h is CRHF, while it is needed if h is weak collision resistance: It is hard to find  $(x,x'),x'\neq x$  such that  $H^s_{k_2}(x)=H^s_{k_2}(x')$  without knowing  $k_2$ .
- **Disadvantage**: IV of H must be modified.

# Hash-based MAC (HMAC)

#### **Construction 15**

 $(\widetilde{\text{Gen}},h)$  is a fixed-length CRHF.  $(\widetilde{\text{Gen}},H)$  is the Merkle-Damgård transform. IV, opad (0x36), ipad (0x5C) are constants.

- $Gen(1^n)$ : Output (s,k).  $s \leftarrow \widetilde{Gen}, k \leftarrow \{0,1\}^n$  u.a.r
- $\blacksquare \ \mathsf{Mac}_{s,k}(m) \colon t := H^s_{IV} \Big( (k \oplus \mathsf{opad}) \| H^s_{IV} \big( (k \oplus \mathsf{ipad}) \| m \big) \Big)$
- $\blacksquare$  Vrfy<sub>s,k</sub>(m,t):  $1 \iff t \stackrel{?}{=} \mathsf{Mac}_{s,k}(m)$

# (In)Security of (Before-)HMAC <sup>4</sup>

We investigate HMAC's security by showing the insecurity of some before-HMAC designs.

- Prepend the key  $H^s(k||x)$ : Vulnerable to length extension attack. Given  $H^s(k||x)$  and the length of x, get the valid tag  $H^s(k||x||x')$  for a new message x||x'.
- Append the key  $H^s(x||k)$ : A collision in the weak CRHF has a collision in the MAC. Recall that there is an appended key for weak CRHF in NMAC.
- Envelope  $H^s(k||x||k)$ : Some known vulnerabilities with this approach, even when two different keys are used. This needs reasonable pseudorandomness assumptions on h.
- Two-key nest  $H^s(k||H^s(k||x))$ : NMAC with 2 keys, HMAC with 1 key

<sup>&</sup>lt;sup>4</sup>from BonehShoup v0.5 p.303

### Remarks on HMAC

- HMAC is based on NMAC which was first published in a paper "Keying Hash Functions for Message Authentication" by Mihir Bellare, Ran Canetti, and Hugo Krawczyk in 1996.
- HMAC became an industry standard (RFC2104) in 1997
- HMAC is faster than CBC-MAC

### Verification timing attacks

```
Keyczar crypto library (Python): def Verify(key, msg, sig_bytes): return HMAC(key, msg) == sig_bytes
The problem: implemented as a byte-by-byte comparison In Xbox 360, a difference of 2.2 milliseconds between rejection times of i vs. i + 1 bytes.

Don't implement it yourself
```

### **Content**

- 1 Message Authentication Codes (MAC) Definitions
- **2** Constructing Secure MAC
- 3 CBC-MAC
- **4** Collision-Resistant Hash Functions
- 5 Hash-based MAC
- 6 Information-Theoretic MACs

### **Definition of Information-Theoretic MAC Security**

It is impossible to achieve "perfect" MAC, as the adversary can output a valid tag with probability  $1/2^{|t|}$  at least.

The one-time MAC experiment Macforge  $_{A,\Pi}^{1-\text{time}}$ :

- 1  $k \leftarrow \mathsf{Gen}$ .
- 2  $\mathcal{A}$  outputs a message m', and is given a tag  $t' \leftarrow \mathsf{Mac}_k(m')$ , and outputs (m,t).
- $\label{eq:macforge} \textbf{3} \ \ \mathsf{Macforge}_{\mathcal{A},\Pi}^{1-\mathsf{time}} = 1 \iff \mathsf{Vrfy}_k(m,t) = 1 \, \wedge \, m \neq m'.$

#### **Definition 16**

A MAC  $\Pi$  is **one-time**  $\varepsilon$ **-secure** if  $\forall$  PPT  $\mathcal{A}$ :

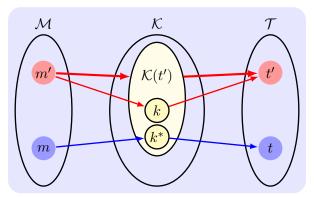

$$\Pr[\mathsf{Macforge}_{\mathcal{A},\Pi}^{1-\mathsf{time}} = 1] \leq \varepsilon.$$

### **Understanding Information-Theoretic MACs**

An adversary will forge the tag in the following steps.

- f I Obtain a tag  $t^\prime$  from a MAC query for a fixed message  $m^\prime$
- 2 Obtain  $\mathcal{K}(t') \stackrel{\text{def}}{=} \{k| \mathsf{Vrfy}_k(m',t') = 1\}$  by using his unlimited computing power
- 3 Output (m,t) using a key  $k^*$  from  $\mathcal{K}(t')$

Question: What if  $\mathcal{K}(t')$  is too large or too small?

### **Construction of Information-Theoretic MACs**

#### **Definition 17**

A function  $h: \mathcal{K} \times \mathcal{M} \to \mathcal{T}$  is a **Strongly Universal (or pairwise-independent) Function (SUF)** if for all distinct  $m, m' \in \mathcal{M}$  and all  $t, t' \in \mathcal{T}$ , it holds that:

$$\Pr[h_k(m) = t \land h_k(m') = t'] = 1/|\mathcal{T}|^2.$$

where the probability is taken over uniform choice of  $k \in \mathcal{K}$ .

#### **Construction 18**

- **Let**  $h: \mathcal{K} \times \mathcal{M} \to \mathcal{T}$  be an SUF.
- Gen:  $k \leftarrow \{0,1\}^n$  u.a.r.
- Vrfy $_k(m,t)$ :  $1 \iff t \stackrel{?}{=} h_k(m)$ . (If  $m \notin \mathcal{M}$ , then output 0.)

### Construction of An SUF

#### Theorem 19

For any prime P, the function h is an SUF:

$$h_{a,b}(m) \stackrel{\mathsf{def}}{=} [a \cdot m + b \mod p]$$

#### Proof.

 $h_{a,b}(m)=t$  and  $h_{a,b}(m')=t'$ , only if  $a\cdot m+b=t \mod p$  and  $a\cdot m'+b=t' \mod p$ . We have  $a=[(t-t')\cdot (m-m')^{-1} \mod p]$  and  $b=[t-a\cdot m \mod p]$ , which means there is a unique key (a,b). Since there are  $|\mathcal{T}|^2$  keys,

$$\Pr[h_k(m) = t \wedge h_k(m') = t'] = \frac{1}{|\mathcal{T}|^2}.$$

# Security of Construction from An SUF

#### Theorem 20

If h is an SUF, Construction is a  $1/|\mathcal{T}|$  – secure MAC.

#### Proof.

Assume that  $\mathcal{A}$  is deterministic and receives tag t' for the message m', where m' is fixed. The pair (m,t) that  $\mathcal{A}$  outputs is a deterministic function of (m',t').

$$\begin{split} \Pr[\mathsf{Macforge}_{\mathcal{A},\Pi}^{1-\mathsf{time}} = 1] &= \sum_{t' \in \mathcal{T}} \Pr[\mathsf{Macforge}_{\mathcal{A},\Pi}^{1-\mathsf{time}} = 1 \wedge h_k(m') = t'] \\ &= \sum_{t' \in \mathcal{T}} \Pr[h_k(m) = t \wedge h_k(m') = t'] \\ &= \sum_{t' \in \mathcal{T}} \frac{1}{|\mathcal{T}^2|} = \frac{1}{|\mathcal{T}|} \end{split}$$

### **Limitations on Information-Theoretic MACs**

**Limitations**: Any  $\ell$ -time  $2^{-n}$ -secure MAC requires keys of length at least  $(\ell+1) \cdot n$ .

#### Theorem 21

Let  $\Pi$  be a 1-time  $2^{-n}$ -secure MAC where all keys are the same length. Then the keys must have length at least 2n.

#### Proof.

Let  $\mathcal{K}(t') \stackrel{\mathrm{def}}{=} \{k | \mathsf{Vrfy}_k(m',t') = 1\}$ . For any t,  $|\mathcal{K}(t')| \leq 2^{-n} \cdot |\mathcal{K}|$ . Otherwise, (m',t') would be a valid forgery with probability at least  $|\mathcal{K}(t)|/|\mathcal{K}| > 2^{-n}$ . The probability that  $\mathcal{A}$  outputs a valid forgery by guessing k from  $|\mathcal{K}(t')|$  is at least

$$\sum_{t'} \Pr[\mathsf{Mac}_k(m') = t'] \cdot \frac{1}{|\mathcal{K}(t')|} \ge \sum_{t'} \Pr[\mathsf{Mac}_k(m') = t'] \cdot \frac{2^n}{|\mathcal{K}|} = \frac{2^n}{|\mathcal{K}|}$$

As the probability is at most  $2^{-n}$ ,  $|\mathcal{K}| \geq 2^{2n}$ . Since all keys have the same length, each key must have length at least 2n.

# **Summary**

- Authentication means existential unforgeability.
- Secure MAC is constructed by using PRF.
- Secure MAC is constructed by using keyed CRHF.
- Information-theoretic MAC security requires very, very long key.
